## SOLID STATE

## Introduction:

i.Matter is divided into solids, liquids and Gases.
ii.Random motion and weak intermolecular forces are characteristic of gases.
iii.In liquid state, free movement of the molecules is limited due to cohesive forces.
iv.In solid state atoms, ions or molecules are arranged orderly in a three dimensional manner due to strong binding forces.Thus Solids have generally high density , low compressibility, very slow or no diffusion. The vapour pressure of solids is generally much less than that of liquids at a definite temperature.
I.TYPES OF SOLIDS: Solids are of two types - crystalline and amorphous solids.

A crystalline solid is one in which the component structural units are arranged in a definite geometrical order which is characteristic of the substances. (Long range order)
Amorphous solids do not have regular and orderly arrangement of the building units of the substances. (Short range order)

## II. Properties of solids

Property

1. Condition of formation
2. Rigidity and hardness
3. Shape
4. Melting points

## Crystalline solids

Slow cooling without disturbing the liquid

Rigid and hard
Definite geometrical configuration

Sharp

Possess plane surfaces
Characteristic X- ray diffraction
bands are given
$\mathrm{KCl} ; \mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O} ; \mathrm{KNO}_{3}$

## Amorphous solids

R apid cooling with churning or disturbance

Rigid and hard
Particles are arranged not in regular order or arranged in short range order

Not sharp and melts over a range of temperature

Not bound by plane surfaces
Diffraction bands are not given
fused silica, glass, pitch, gelatinous $\mathrm{Al}(\mathrm{OH})_{3}$

When Quartz is melted and rapidly cooled an amorphous solid result, in which $\mathrm{SiO}_{4}$ chains are irregular.
i.Amorphous solids can be moulded or blown into articles of different shapes.
ii.Amorphous solids have a tendency to flow, but very slowly. Hence, they are also called 'pseudo solids' or 'super cooled liquids'. Amorphous solids are 'isotropic' i.e their physical properties are same in all directions.
iii.Crystalline solidsare 'anisotropic' i.e some of their physical properties like electrical resistance or refractive index show different values when measured along different directions.
iv.Amorphous solids are used in domestic constructions or appliances like photo voltaic cells, where the sunlight is transformed into electricity.
III.Classification of crystalline Solids: -These are classified into ionic, covalent, metallic and molecular solids according to the nature of the building units, chemical bonding and the intermolecular forces in the crystal.
The characteristics of various types of solids are given in the table.

| Type of solid | Constituent particles | Bonding or attractive forces | Examples | Physical nature | Electrical conductivity | Melting point |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Molecular solids <br> (i) Non polar | Molecules | London or Dispersion forces | $\begin{aligned} & \mathrm{I}_{2}, \mathrm{CO}_{2}(\mathrm{~s}), \\ & \mathrm{Ar}(\mathrm{~s}) \end{aligned}$ | Soft |  | Very low |
| (ii) Polar |  | Dipole - dipole interactions | $\begin{aligned} & \mathrm{HCl}(\mathrm{~s}), \\ & \mathrm{SO}_{2}(\mathrm{~s}) \end{aligned}$ | Soft | Extremely low | Low |
| (iii) Hydrogen bonded |  | Hydrogen bonding | $\mathrm{H}_{2} \mathrm{O}$ (ice) | Soft |  | Low |
| Ionic solids | Ions | Coulombic or electrostatic | $\begin{aligned} & \mathrm{NaCl}, \mathrm{MgO}, \\ & \mathrm{ZnS}, \mathrm{CaF}_{2} \end{aligned}$ | Hard but brittle | Insulators in solid state but conductors in molten state and in aqueous solutions | High |
| Metallic solids | Positive ions in a sea of delocalised electrons | Metallic bonding | $\mathrm{Fe}, \mathrm{Cu}, \mathrm{Ag}$, $\mathrm{Mg}, \mathrm{Sn}, \mathrm{Au}$ | Hard but malleable and ductile | Conductors in solid state as well as in molten state | Moderate to high |
| Covalent or network solids | Atoms | Covalent bonding | $\mathrm{SiO}_{2}$ (quartz), <br> SiC, AlN,BN, <br> C (diamond) <br> C (graphite) | Very hard, except graphite | Insulators, except graphite | Very high <br> High |

IV.Coordination Number of Crystals: The coordination number of an atom or ion in solid is the number of nearest neighbours for that atom or ion

Eg:

1) In NaCl crystal, coordination number of $\mathrm{Na}^{+}$ion as well as $\mathrm{Cl}^{-}$ion is 6 .
2) Coordination number of $C$ in diamond is 4
3) In Silica, coordination number of ' Si ' is 4 while that of oxygen atom is 2
4) In metal lattices the coordination number of a metal atom is usually 8 or 12 .
5) In ZnO , coordination number of $\mathrm{Zn}^{+2}$ ion as well as $\mathrm{O}^{-2}$ ion is 4 .
6) In CsCl crystal, coordination number of $\mathrm{Cs}^{+}$ion as well as $\mathrm{Cl}^{-}$ion is 8 .

## V. Limiting Radius ratio:-

The shape of ionic crystal and Co-ordiantion number depends on cation to anion radius ratio (i.e. $r_{c} / r_{a}$ value) called 'Limiting Radius Ratio'

| Limiting radius | Coordination | Shape or |
| :---: | :---: | :--- |
| ratio | number | structure |
| $<0.155$ | 2 | Linear |
| $0.155-0.225$ | 3 | Planar triangle |

| $0.225-0.414$ | 4 | Tetrahedral |
| :--- | :--- | :--- |
| $0.414-0.732$ | 4 | Square planar |
| $0.414-0.732$ | 6 | Octahedral |
| $0.732-0.999$ | 8 | Body centred |

Ex.1.The $\mathbf{r}_{\mathrm{c}} / \mathbf{r}_{\mathrm{a}}$ for NaCl is $\mathbf{0 . 5 2}$. Thus NaCl has F .C.C Lattice
2. The $\mathbf{r}_{\mathrm{c}} / \mathbf{r}_{\mathrm{a}}$ for CsCl is $\mathbf{0 . 9 3}$. Thus CsCl has b.c.c Lattice
VI. Metallic Bonding: Metallic bond is neither ionic nor covalent in nature. Three theories are familiar in explaining bonding in metallic solids.

1. Electron sea model of Drude and Lorentz
2. Valence bond theory of Linus Pauling
3.Molecular orbital theory of Hund and Mulliken

## (1)ELECTRON SEA MODEL:

According to this in a metallic solid all metal atoms loose their valence electrons to form positive metal ions (called Kernels) and a sea of electrons (called delocalised or mobile electrons). As a result an electrostatic force of attraction develops between Kernels and free electrons which is called metallic bond. It explains electrial conductivity and metallic lustre
DEFECTS: Failed to explain quantitative calculations for the lattice energies of ionic compounds.

## (2) VALENCE BOND THEORY or Resonance theory:

According to this theory, The metallic bond is essentially a polar or a non polar covalent bond.
The covalent bond involves resonance between a number of structures having one electron and electron pair bonds. Resonance occurs due to the possibility of insufficient valence electrons for the formation of electron pair bonds with each atom of the metal. Resonance involves both covalent and ionic linkages.
DEFECTS: It does not explain the conduction of heat in solids and their lustre. It does not explain the retention of metallic properties in liquid state.

## VII. CLOSE PACKING IN THREE DIMENSIONS

(i) SIMPLE CUBIC ARRANGEMENT: -

In this arrangement the spheres can be arranged in a layer such that each metal atom is in touch with four other atoms.A second layer of spheres is superposed on the first layer such that the spheres of the second layer are exactly above the spheres of first layer.

* Coordination number of each sphere is 6 .
*In this structure the percentage space occupied is $52 \%$ \& the remaining $48 \%$ space is void. Eg: Polonium
(ii) HEXAGONAL CLOSE PACKED (HCP) ARRANGEMENT

It is also called as AB AB AB ...... type arrangement.
In any layer of spheres every sphere is in contact with six other spheres.
The vacant spaces between the spheres known as holes or voids
If the second layer of spheres is arranged by placing these spheres over the holes in the first layer, three of the six holes formed are only covered by the spheres. Out of the six holes; only three are covered by the spheres. Third layer of spheres can be superposed on the spheres of this layer directly over the spheres of the first layer. i.e third layer is the repetition of the second layer.
In HCP each sphere is in contact with 6 spheres in its own layer. It also touches ' 3 ' spheres in the above layer and 3 spheres in the below layer. Thus the co-ordination number is 12 .
In this arrangement atoms occupy $74 \%$ of the available space and thus have $26 \%$ vacant space.
E.g. $\mathrm{Be}, \mathrm{Mg}, \mathrm{Tl}, \mathrm{Cd}, \mathrm{Co}, \mathrm{Zn}, \mathrm{Ce}, \mathrm{Ti}, \mathrm{Os}, \mathrm{Ru}$, etc.
(iii) BODY CENTERED CUBIC (BCC) ARRANGEMENT

This arrangement is obtained when the spheres in the first layer are slightly opened up, ie. None of the spheres touches each other.I $n$ the second layer, the spheres are placed at the top of hollows in the first layer. In the third layer, spheres are placed exactly above the first layer. Each sphere in this system of packing is in contact with eight spheres, four in the lower layer and four in the upper layer. Thus the co-ordination number is 8 .
In this arrangement atoms occupy $68 \%$ of the available space and thus have $32 \%$ vacant space.
This lattice is quite common for Alkali metals.
Eg. Na, K, Rb, Cs, Ba, Cr, Mo, W
(iv) FACE CENTERED CUBIC (FCC) ARRANGEMENT OR CUBIC CLOSED PACKING. This type of arrangement is known as ABC ABC ABC ...... arrangement.
In this arrangement, the spheres of the second layer are placed in the holes formed by the first layer and the spheres in the third layer may be placed in the hollows of the second layer such that the sphere is not exactly above the sphere in the first layer.

* Coordination number of each sphere is 12 .

In this arrangement atoms occupy $74 \%$ of the available space and thus have $26 \%$ vacant space. $\mathrm{Eg}:-\mathrm{Al}, \mathrm{Cu}, \mathrm{Au}, \mathrm{Pb}, \mathrm{Pt}, \mathrm{Pd}, \mathrm{Ni}$ and Ca .

## VIII.UNIT CELL IN TWO DIMENSIONAL \& THREE DIMENSIONAL LATTICES:

(i) SPACE LATTICE: The pattern of points which indicates the arrangement of particles in the crystal is known as space lattice.
Ex.The space lattice of sodium chloride is obtained by joining the space lattices of $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions.
(ii)UNIT CELL: - The smallest three dimensional portion of the space lattice which when repeated again and again in different directions produces the complete space lattice is called the unit cell. Types of unit cells:
i) Primitive or simple unit cell: The unit cell without a point inside is known as 'primitive unit cell' i.e., the particles are present only at the corners of the unit cell.
Ii) Centered unit cell: Contains a point inside is known as centered unit cell. Eg. F.C.C, B.C.C, End face centered unil cell.
a) In Face-centred unit cell: in addition to the particles at the corners, there is one particle present at the centre of every face.
It has 14 lattice points ( 8 corners and 6 face centres)
b) In End face centered unit cell: in addition to the particles at the corners, there is one particle in the centre of two opposite faces.
It has 10 lattice points ( 8 corners and 2 face centres)
c) In Body-centred unit cell: in addition to the particles at the corners, there is one particle present within the body of the unit cell.
It has 9 lattice points ( 8 corners +1 body centre)

## IX.CRYSTAL SYSTEMS: -

On the basis of symmetry and set of crystallographic parameters crystals are classified into 14 types of crystal lattices (Bravais lattices) and 7 different types of crystal systems.
The intercepts on the $\mathrm{X}, \mathrm{Y}$ and Z axes are designated as $\mathrm{a}, \mathrm{b}$ and c respectively. The angle between the Y and $Z$ axes is, that between $X$ and $Z$ axes is and that between $X$ and $Y$ axes is.

Seven primitive cells and their possible variations as centred unit cells

| Crystal system | Possible variations | Axial <br> distances <br> or edge <br> lengths | Axial angles | Examples |
| :---: | :---: | :---: | :---: | :---: |
| 1. Cubic | Primitive,f.c.c, Body-centred | $\mathrm{a}=\mathrm{b}=\mathrm{c}$ | $\alpha=\beta=\gamma=90^{\circ}$ | NaCl, Zinc blende, Cu |
| 2.Tetragonal | Primitive, <br> Body-centred | $\mathrm{a}=\mathrm{b} \neq \mathrm{c}$ | $\alpha=\beta=\gamma=90^{\circ}$ | $\begin{aligned} & \text { White tin, } \mathrm{SnO}_{2} \quad \mathrm{TiO}_{2}, \\ & \mathrm{CaSO}_{4} \end{aligned}$ |
| 3.Orthorhombic | Primitive, <br> Body- centred, <br> Face-centred <br> End-centred | $\mathrm{a} \neq \mathrm{b} \neq \mathrm{c}$ | $\alpha=\beta=\gamma=90^{\circ}$ | Rhombic sulphur $\mathrm{KNO}_{3}, \mathrm{BaSO}_{4}$ |
| 4.Hexagonal | Primitive | $\mathrm{a}=\mathrm{b} \neq \mathrm{c}$ | $\begin{aligned} & \alpha=\beta=90^{\circ} \\ & \gamma=120^{\circ} \end{aligned}$ | Graphite, ZnO , CdS |
| 5. Rhombohedral or Trigonal | Primitive | $\mathrm{a}=\mathrm{b}=\mathrm{c}$ | $\alpha=\beta=\gamma \neq 90^{\circ}$ | Calcite $\quad\left(\mathrm{CaCO}_{3}\right), \quad \mathrm{HgS}$ (cinnabar), $\mathrm{KMnO}_{4}, \mathrm{Bi}, \mathrm{As}, \mathrm{Sb}$ |
| 6.Monoclinic | Primitive <br> End-centred | $a \neq b \neq c$ | $\begin{aligned} & \alpha=\gamma=90^{\circ} \\ & \beta \neq 120^{\circ} \end{aligned}$ | $\mathrm{Na}_{2} \mathrm{SO}_{4} \cdot 10 \mathrm{H}_{2} \mathrm{O}$ monoclinic sulphur, |
| 7.Triclinic | Primitive | $a \neq b \neq c$ | $\alpha \neq \beta \neq \gamma \neq 90^{\circ}$ | $\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}, \mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ |

*Ice \& Quartz may give hexagonal or trigonal crystals
Space lattices of crystal system

| S.No. | Crystal system | Number.of <br> Bravias latices | Common names of the lattices |
| :--- | :--- | :---: | :--- |
| 1 | Cubic | 3 | Simple cubic, face centred and body centred <br> cubes |
| 2 | Tetragonal | 2 | Simple cubic and body centered <br> tetragonalprisms |
| 3 | Rhombic | 4 | Rectangular, body centered, face centred and <br> end centred rhombic prisms |
| 4 | Hexagonal | 1 | Hexagonal prism |
| 5 | Trigonal | 1 | Rhombohedral |
| 6 | Monoclinic | 2 | Primitive and edge centered |
| 7 | Triclinic | 1 | Triclinic primitive |

## X.characteristics of a crystal lattice

a) Each point in a lattice is called lattice point or lattice site.
b) Each point in a crystal lattice represents one constituent particle which may be an atom, a molecule or an ion.
c) Lattice points are joined by straight lines to bring out the geomentry of the lattice.

## XI. Position of ions in cubic unit cell and contribution to unit cell

Position of ion Number of Contribution
in unit cell unit cells of ion to each sharing unit cell

| Centre of the body | 1 | 1 |
| :--- | :--- | :---: |
| Centre of the face | 2 | $1 / 2$ |
| Edge of a face | 4 | $1 / 4$ |
| Corner of cube | 8 | $1 / 8$ |

## EFFECTIVE NUMBER OF ATOMS (Z) IN UNIT CELL: IN SIMPLE CUBIC IS 1, B.C.C IS 2 AND F.C.C IS 4

## XIII.INTERSTITIAL VOIDS:

The empty spaces between the three dimensional layers are known as voids or holes. There are two types of common voids possible. They are called tetrahedral and octahedral voids. These are also called interstices.
Tetrahedral void: A hole formed by three spheres of a layer in contact with each other and also with a sphere on the top or bottom layer is a hole between four spheres. The spheres are arranged at the vertices of a regular tetrahedron. Such a hole is called tetrahedral void.
*Radius ratio of tetrahedral void $=0.225 \mathrm{X}$ Radius of atom

Octahedral void: A hole formed by three spheres of a hexagonal layer and another three spheres of the adjacent layer is a hole between six spheres. The spheres are arranged at the vertices of a regular octahedron. Such a hole is called octahedral void.

*Radius ratio of octahedral void, $=0.414 \mathrm{X}$ Radius of atom
If there are ' $n$ ' atoms present in the unit cell of close packed structure the number of tetrahedral voids are ' $2 n$ ' and the number of octahedral voids are ' $n$ '.
XIV. Relation between atomic radius and the edge of the Unit cell. (For elements)
I.In simple cubic structure: edgelength (a) $=2 \mathrm{r}$

Distance between nearest neighbours $(\mathrm{d})=2 \mathrm{r}=\mathrm{a}$
Atomic radius ( r ) $=\mathrm{a} / 2$.
ii.In body centred cubic lattice:

Body diagonal length $=4 r=\sqrt{3} \mathrm{a}$
Distance between nearest neighbours (d) $2 \mathrm{r}=\frac{\sqrt{3}}{2} \times a=0.866 \mathrm{a}$
Atamic radius ( r ) $=\frac{\sqrt{3}}{4} \times a=0.433 \mathrm{a}$
iii.In face centred cubic lattice: $\boldsymbol{-}$ face diagonal length $(4 \mathrm{r})=\sqrt{2} a$

Distance between nearest neighbours $(\mathrm{d})=2 \mathrm{r}=\frac{a}{\sqrt{2}}=0.707 \mathrm{a}$
Atomic radius (r) $=\frac{a}{2 \sqrt{2}}=0.3535 \mathrm{a}$
XV. Packing Efficiency: The percentage of total space filled by the particles in a solid is called packing efficiency.
Packing efficiency $=$ packing fraction X 100.
Packing fraction $=\frac{\text { Volume occupied by all the spheres in the unit cell }}{\text { Total volume of the unitcell }}$

## In both H.C.P and C.C.P structures

Packing efficiency $=\frac{\pi \sqrt{2}}{6} \times 100=0.74 \mathrm{X} 100=74 \%$
In B.C.C structure packing efficiency $=\frac{\pi \sqrt{3}}{8} \times 100=0.68 \mathrm{X} \quad 100=68 \%$
In simple cubic lattice: Packing efficiency $=\frac{\pi}{6} \times 100=0.524$ X $100=52.4 \%$

* Hexagonal close - packing and cubic close - packing are more efficient than any other sort of arrangement.
